

EXPERIMENT NO : 10

Aim: To learn Dockerfile instructions, build an image for sample web application using DOCKERFILE Theory :

Docker is a platform designed to make it easier to create, deploy, and run applications by using containers. Containers allow a developer to package up an application with all parts it needs, such as libraries and other dependencies, and ship it all out as one package. Here's a detailed look at the basics of Docker:

1. What is Docker?

Docker is an open-source platform that automates the deployment of applications inside lightweight, portable containers. A container is a standard unit of software that packages up code and all its dependencies so the application runs quickly and reliably from one computing environment to another.

2. Key Concepts in Docker

Containers

- Definition: Containers are isolated environments where applications run with everything they need to function.
- Features: They are lightweight, fast, and share the host OS kernel, making them more efficient than virtual machines.

Images

- Definition: An image is a read-only template used to create containers. It includes the application code, libraries, and other dependencies.

- How it works: You build an image, then run a container based on that image.

Docker Engine

- The core component of Docker that runs and manages containers.
- It has two main parts:
 - Server: A long-running daemon process (**dockerd**) that manages containers.
 - Client: The command-line interface (**docker**) that users interact with.

Docker Hub & Registry

- Docker Hub: A cloud-based registry service where Docker images are stored and shared.
 - Registry: A service for storing and distributing Docker images. Docker Hub is the default registry, but you can set up private registries.
-

3. How Docker Works

- Dockerfile: A script that contains instructions to assemble a Docker image. It defines the base image, application code, and dependencies.
 - Building Images: Using the command **docker build**, Docker reads the Dockerfile and creates an image.
 - Running Containers: Using **docker run**, Docker starts a container from an image.
-

4. Why Use Docker?

- Portability: Containers can run on any system that has Docker installed, regardless of the underlying hardware or OS.
- Consistency: The application runs the same way in development, testing, and

- Isolation: Each container is isolated from others, preventing conflicts between applications.
- Efficiency: Containers are lightweight, using fewer resources compared to virtual machines.

5. Basic Docker Commands

- `docker --version`: Check Docker version.
- `docker pull <image>`: Download an image from Docker Hub.
- `docker build -t <name> .`: Build an image from a Dockerfile.
- `docker run <image>`: Run a container from an image.
- `docker ps`: List running containers.
- `docker ps -a`: List all containers (including stopped ones).
- `docker stop <container_id>`: Stop a running container.
- `docker rm <container_id>`: Remove a container.
- `docker rmi <image_name>`: Remove an image.

6. Docker Compose

- A tool for defining and running multi-container Docker applications.
- Uses a YAML file (`docker-compose.yml`) to configure services, networks, and volumes.
- Command: `docker-compose up` to start all services defined in the file.

- Microservices Architecture: Running different microservices in isolated containers.
- Continuous Integration/Continuous Deployment (CI/CD): Automating testing and deployment processes.
- DevOps and Infrastructure as Code: Simplifying the deployment of complex applications.

Output:

```

Conclusion :

Docker revolutionizes the software development and deployment process by providing a powerful platform for containerization. By encapsulating applications and their dependencies into lightweight, portable containers.
